

# RECeUS: Ratio Estimation of Censored Uncured Subjects, A Different Approach for Studying Sufficient Follow-Up in Studies of Long-Term Survivors

Subodh Selukar and Megan Othus

## MOTIVATION

### Mixture-Cure Models

Mixture-cure models assume the observed data arise from a mixture of cured and uncured subpopulations

### Sufficient Follow-Up

If a study ends too early, the right tail of the distribution may not be identifiable

### Problem

Existing methods may:

- Falsely conclude sufficient follow-up, causing bias
- Falsely claim insufficient follow-up, possibly leading to additional, costly data collection

## PROPOSAL

### RATIO ESTIMATION OF CENSORED UNCURED SUBJECTS

$$\hat{r}_n = \frac{\hat{S}_{uc}(\tau)}{\hat{S}(\tau)}$$

- $\hat{S}_{uc}(\tau)$ : estimate of proportion uncured remaining at study end
- $\hat{S}(\tau)$ : estimate of proportion overall remaining at study end

### RECeUS Advantages

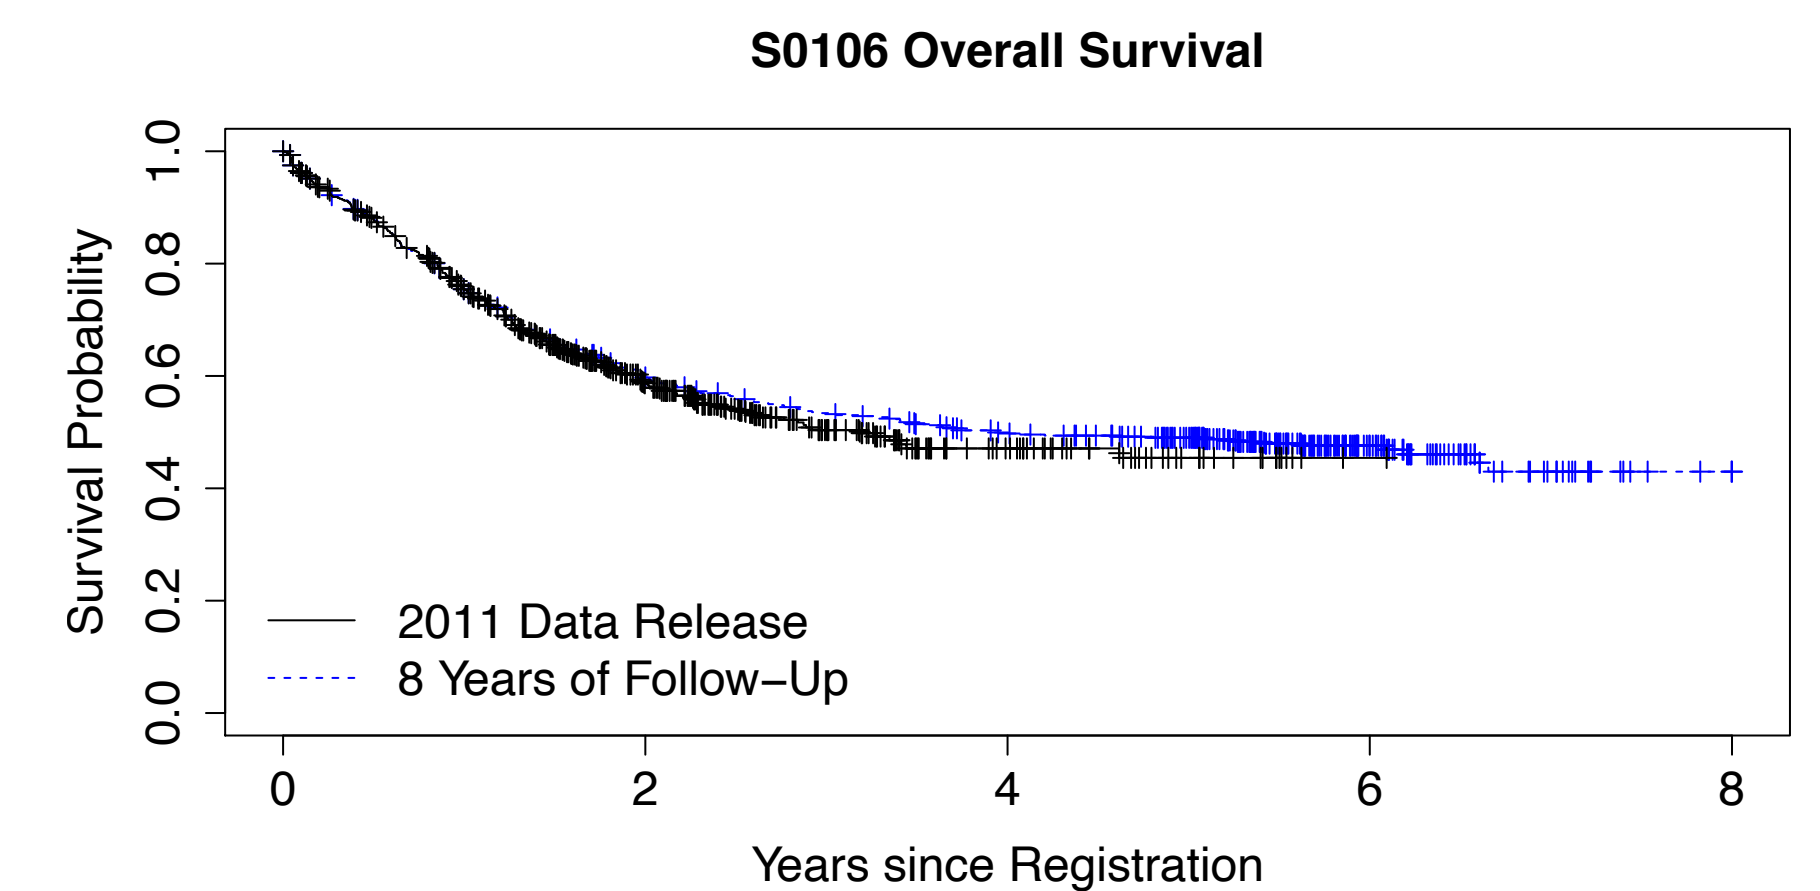

- Flexible
  - Parametric or semiparametric mixture-cure models
- Interpretable
  - Standardized version of proportion uncured remaining at study end
  - Smaller  $\hat{r}_n$ , cure model more appropriate

## SIMULATIONS

Truth	Rates of Concluding Cure Model Appropriateness*		
	RECeUS	Maller & Zhou (1994)	Shen (2000)
Cure Model Appropriate?			
No	Low	High	Low
Yes	High	High	Low

\*Based on simulations from Weibull, Log-Logistic and Gamma mixture-cure distributions, where RECeUS used an AIC-based model selection procedure to estimate  $\hat{r}_n$  and a criterion of (1)  $\hat{r}_n < 0.05$  and (2) estimated cure fraction of at least 2.5%

## DATA EXAMPLES

Cure Model Appropriate?	RECeUS	Maller & Zhou (1994)	Shen (2000)
S1117: No	✓	✗	✓
S0106: Yes	✓	✓	✗

✓ Correct Decision

✗ Incorrect Decision

## Conclusion

RECeUS accurately classifies when a cure model is or is not appropriate in simulations and data examples
