

Probabilistic Methods in Time Series Analysis: A Case Study Sarah Cameron, Valerie Schnapp, Lindsay Truong

Introduction

Modeling real-world time series data poses unique challenges such as:

- Infrequent Reporting
- Data Inconsistences
- Nonlinear Behavior

A probabilistic approach helps circumvent these issues by natively handling missing, noisy data while providing a result with measurable uncertainty.

Weekly aggregation revealed a seasonal pattern and was the basis for all analysis

Objectives

- 1. Forecast future timeliness
- 2. Derive a data-driven timeliness policy goal 4. Detect performance outliers
- 3. Characterize process behavior

Model Technique 1: Change Point Analysis

Change Point Analysis was used to determine the effect of policy change on process and stage timeliness.

Change Point Analysis uses Hidden Markov Model (HMM) to detect structural changes in behavior. HMM uses hidden layers to detect the change points in the data and an observed layer for the time series.

Model Technique 2: Gaussian Process Regression

Gaussian Process Regression (GPR) is a Bayesian regression technique that flexibly adapts to the data, assumes noisy data and finds a distribution that best characterizes the data.

Booz | Allen | Hamilton®

after a policy change that was enacted in 2017.

Gaussian Process Regression was used to characterize process behavior and identify performance outliers.

Model Technique 3: Structural Time Series

Structural Time Series was used to forecast timeliness behavior and anticipate backlog.

$$f(t) = f_1(t) + f_2(t) + \cdots + f_n(t) + \varepsilon; \ \varepsilon \sim \mathcal{N}(0, \sigma^2)$$

Conclusion: By incorporating relevant time series components, timeliness was forecasted with narrow confidence.
